1544. THE APPLICATION OF VI-AGGLUTINATION FOR THE DETECTION OF CARRIERS OF TYPHOID BACILLI - A Vi haemagglutinatio felhasználása a typhius bacillusgazzdakutatásban - Kubinyiné S. M., Incze P. and Vácz L. Országos Kozegészségügyi Int. Bakteriol. Oszt., Budapest - ORV. HETIL. 1958, 99/32 (1093-1096) Tables 3

A stable Vi-antigen, prepared by the acetone method from strain Vi-965, proved to be insufficiently specific. Lipopolysaccharide, extracted from the same strain by the Westphalian method, gave better results. A specific and sensitive reaction occurred with the Vi-antibodies in the blood of carriers. More extensive experiments with this method are both possible and necessary.

500 principles in the manufacture of hip products with a 14% acetic acid content. A. Lissitzky and E. Dreyfus, document dated 28/4/1951 U.S. Patent No. 2,871,111. The process involved a ripe hard starch; then the starch was chlorinated about 50% emulsified between wooden troughs containing a 10% citric acid soln., and after that about 10% methanol, left to stand at 38° for 5-18 hrs., and then dried in a drying oven. The starch was cooled, then washed with water at 40-45°. The acetic acid content of the starch was found to be about 10,000 mg./kg. The starch was quite waxed over therefore it was mixed with cellulose acetate in a ratio of 1:8. About 30 ml. of cellulose acetate was added to each 100 g. requirement of starch.

1550. Determination of dehydracetic acid in fruit juices. J. Kevei and A. Inczédy (*Magyar Akad. Foly.*, 1954, 64 (4), 108-108; *Zs. Erdőgyógyászat*, 1954, Abstr. No. 40,285).—Fruit juice is extracted with ether and the sum of aldehydes plus dehydracetic acid (I) is determined by treating the extract with conc. KOH soln, and measuring the colour formed with salicyaldehyde in a Pulfrich photometer. The colour due to the aldehydes is then determined on the distillate from a sample of neutralised juice, and the amount of I present is found by difference. The method permits the determination of 0.03 to 0.50 per cent. of I.

13. Dutch photometric method for the determination of small amounts of aluminum in aluminum(II) boracite
L. Gidev, L. J. Verheyen, Acta Chimica Scandinavica, Vol. 4, 1954, pp. 211-214.

A photometric method for use in plant laboratories was elaborated to determine minute quantities of aluminum in aluminum. Diphenyl carbonyl proved to be the best colour reagent. Conversion of aluminum(II) boracite to aluminum(IV) ions can be carried out by oxidation with potassium permanganate or, when traces of iron or of iron are present, by the silver nitrate and ammonium peroxo-diphosphate method. Ions of heavy metals interfere with the determination are eliminated by precipitation with hydrogen sulphide. Thus the determination can be carried out with an error not exceeding $\pm 1\%$ even if the alumina content is only 0.01%.

✓ Kinetic data on the decomposition of hydrogen peroxide in an alkaline medium. László Erdély and János Inczid
(Budapest Inst. Technol.). Magyar Tudományos Akad.
Köz. Tudományos Ozsidájának Kiadásának 5, 513-3
(1955). — The decompo. rate of H_2O_2 was studied as a function

(Off) of pH (in buffered solns.), temp., and glass area of the vessel. The postulated mechanism involves decompo. of a $H_2O_2-OH^-$ transition ion on the wall of the vessel. At const. temp. and wall area, independent of the kind of glass, the rate increases with pH to a max., where $pH = -\log A^* + 12$ (K = dissoci. const. of H_2O_2), then decreases. At this pH the reaction is of the 2nd order, whereas at other pH values it is of a fractional order. The activation energy (20.00 cal./mol.) detd. at pH = 12, at different temps., is independent of wall area. The frequency factor in the Arrhenius equation is a function of wall area. The decompo. rate is directly proportional to wall area below pH 12, and proportional to the square root of the surface ratio above pH 12. At all pH values the rate extrapolated to zero wall area becomes zero; this indicates that the transition ion decomps. exclusively on the wall. A period of induction was noted for the reaction. Also in Acta. Chim. Acad. Sci. Hung. 7, No. 1-2, 93-115 (1955) (in German) (English summary).

21. Data on the kinetics of the decomposition of hydrogen peroxide in alkaline medium. (In German) L. Erdely

L. Inczedy. Acta Clinica Academiae Scientiarum Hungaricorum, Vol. 7, 1953, No. 1-2, pp. 93-115, 7 figs., 3 tabs.

Based on a theoretically derived reaction equation the decomposition process proved to be of the second order. Experimentally however the second order was found only at the pH value of maximum decomposition. The activation energy of the decomposition was calculated from the rate constants established at different temperatures for the pH values of maximum decomposition. The activation energy proved to be independent of the dimensions of the enclosing glass surface. A linear relationship was found to exist between the decomposition rate and the surface area below pH 12. Above this value the decomposition rate varies as a function of the square root of the surface. The alkaline decomposition of hydrogen peroxide was fulfilled by a starting period possibly due to the formation of a hypothetical intermediate. It is the deformation of this intermediate product on the glass surface which actually yields the well known decomposition products.

Title: Production of Hydroxyl Amine by the Raschig Method

Original

Periodical: Magyar kem. folyoirat, 1956, Vol 62, No 5, 165-170 (published in Hungarian with a German summary)

Abstract: The conditions for the production of NH_2OH by the Raschig method have been investigated. The most suited method was found to be one which had been published earlier (L. Urbanek, Mezogazd. Kutatasok, 1933, Vol 6, 334) in which the optimum mole ratio was found to be $\text{NaHSO}_3 : \text{NaNO}_2 = 1:1.95$. The effect of pH, temperature, and mixing rate on the production of NH_2OH was investigated. At optimum conditions the yield of end product can exceed 90%.

Title : Concerning the Reaction Taking Place Between Hydrogen Peroxide and Hypohalogenites in an Alkaline Medium.
Orig Pub : Acta chim. Acad. sci. hung., 1957, 11, No 1-2, 125-135

Abstract : Decomposition of H_2O_2 in presence of NaIO and NaBrO at pH 7-12 and 40° is of 1-st order in relation to concentration of H_2O_2 and hypohalogenite; reaction velocity passes through a maximum at pH 10.5 for NaIO and at pH 11.5 for NaBrO. The stage that limits the reaction velocity is $I^- + H_2O_2 \rightarrow IO^- + H_2O$ and $BrO^- + H_2O_2 = Br^- + H_2O + O_2^-$.

Explosions, Topochemistry, Catalysis.

Abs Jour : Ref Zhur - Khimiya, No 8, 1958, 24209

The authors assume that in the mechanism of the reaction takes part an intermediate complex (or radical) the formation of which is promoted by the wall. Reaction of H_2O_2 with HOCl, within the interval of pH 2-13 and at a temperature of 0° and 40° takes place according to the stoichiometric equation $HOCl + H_2O_2 \rightleftharpoons H_2O + O_2 + HCl$. Reaction velocity has 2 maxima at pH 7 and 11. To different pH intervals correspond different reaction mechanisms.

✓ Decomposition of hydrogen peroxide in an alkali solution in the presence of a copper citrate complex. L. Erdik and J. Inczédy (Tech. Univ., Budapest). *Acta Chim. Acad. Sci. Hung.* 17, 93-111 (1958) (in German).—A study of H_2O_2 decompn. in alk. soln. showed that on increasing pH values in the presence of a Cu^{++} -citrate complex the rate of decompn. rises linearly, whereas in pure alk. soln. there is a max. at pH 12. In the decompn. the homogeneous process is clearly discernible from the much slower process of O development on the walls. The HO_2 radical and intermediates of a brown Cu peroxy compd. (I) play a role in the homogeneous process. The rate of the over-all process is determined by stationary I concns. and the concn. of perhydroxyl ions. When the initial mole ratio of H_2O_2 and Cu^{++} ions exceeds 100, the stationary concn. of I is stable at a larger interval, within which a 1st-order reaction is observed. The const. stationary concns. are approx. independent of pH and of H_2O_2 concn. The activation energy of decompn. is 12 kcal./mole. Perhydroxyl ions are dominant in the decompn. and their activity is reduced by undissolved H_2O_2 mols. The homogeneous process is nearly independent of glass surface area in contact with the soln., but the rate of O development is proportional to surface area and, at high surface/vol. ratios, can approach the rate of decompn.

"The Effect of ATP Spofa on the Experimental Hypertrophy of the Rat Cardiac Muscle. II. Study of Electrocardiographic Changes."

Prague, Ceskoslovenska Farmacie, Vol 15, No 8, Oct 66, pp 399-402

Abstract [Authors' English summary modified]: Changes in electrocardiographs of Wistar strain female rats in whom hypertrophy was induced by daily swimming until exhaustion for 9 weeks were investigated. 0.12 mg of ATP Spofa was administered to one group of the rats. The rats that did not receive the ATP showed a deviation of the electrical axis to the right after 3 weeks, and to the left after 9 weeks. No deviation to the left was found in rats who received ATP. ATP inhibited heart hypertrophy; small doses increased the heart rate. 2 Figures, 1 Table, 12 Western, 8 Czech, 1 Russian, 4 Hungarian references. (Manuscript received 30 Mar 66).

TITLE: Isomorphic copolycondensation of polyethyleneterephthalate with 7-
and (6-) carboxy-, 2-methylol-, 1,4-benzodioxan

CITED SOURCE: Izv. AN LatvSSR, Ser. khim., no. 3, 1963, 367-369

TOPIC TAGS: copolymer, isomorphic copolycondensation, polyethyleneterephthalate, benzodioxan copolymer, polymer flexibility, polymer density

TRANSLATION: The isomorphic copolycondensation of polyethyleneterephthalate (density of the polymer after heating for 3 hours at 180°C = 1.386 g/cc) with 7- (and 6-) carboxy-, 2-methylol-, 1,4-benzodioxan in a melt (270-280°C/1-2 mm Hg, 4 hours in an argon atmosphere) in the presence of Zn acetate, with stirring, leads to an increase in the crystallinity and packing density of the polymer, as revealed by an increase in density to 1.400 g/cc. The increase in flexibility of the macromolecules following isomeric displacement leads to an increase in the number of times the fiber can be drawn out in the cold. O. IV

TYPE: Synthesis of polyesters containing active functional groups in the macromolecules

CITED SOURCE: Izv. AN Latv. SSR. Ser. khim., no. 3, 1964, 303-305

TOPIC TAGS: polyester synthesis, interphase polymerization, active functional groups, polyester property

REMARKS: Polyesters with COOH groups in the side chain were obtained by interphase polymerization of 4,4'-dihydroxybiphenyl with the acyl chlorides of phthalic acid and terephthalic acid in the presence of NaHCO₃. The authors note that the polyesters obtained have a high degree of crystallinity and that acid anhydrides containing carboxylic acid groups are more effective than phthalic acid. They were polymerized in acetone at 60°C for 10 hours. The polymers had a melting point near the illus.

Na_2CO_3 . The polyesters obtained had melting points of 102 to 140°C. (from aliphatic acids) or 375-400°C (from terephthalic acid) and a reduced viscosity (0.5% solution in cresol) of 0.38 to 0.24. They were soluble in alcohol, dimethylformamide and water at pH 9. The polyester yield was $\leq 12\%$ when using Na_2CO_3 as the acceptor of the precipitating HCl, as well as in the case of the

ABSTRACT: The description and drawings of a Hand saw Tooothing and
notching die are given. This stamp is adapted to cut
teeth of any shape and to pierce round holes as well.
The design of this die permits cutting teeth in a saw
blade if its thickness does not exceed 1.8 mm. The
method and appropriate technique for cutting off worn
teeth and making new teeth of any shape are recommended.
instruction for servicing the stamp is also provided.

TITLE: On the Temperature Dependence of the Plasticity of Alloys in Solid-Liquid State (O temperaturnoy zavisimosti plastichnosti splavov v tverdo-zhidkem sostoyanii)

PERIODICAL: Nauchnyye doklady vysshey shkoly. Metallurgiya, 1958, Nr 1, pp 99-103 (USSR)

ABSTRACT: The plasticity constants in the crystallization intervals of alloys were investigated. Solid aluminum alloys of the system Al - Mg - Zn - Cu were used as initial material for the samples. The temperature dependence of the breaking point and the relative expansion of the alloys above and below the solidus line for the alloy B 95 were investigated. This investigation showed that the breaking point drops rapidly to the solidus line and slowly decreases according to the rise of temperature in the crystal interval. Furthermore the temperature dependence of the relative expansion was investigated. Alloys below the solidus temperature have higher plasticity. The transition through the solidus from the solid to the liquid state is accompanied by a jump-

Card 1-2

SCV/163-58-1-19/53

On the Temperature Dependence of the Plasticity of Alloys in Solid-Liquid State

like drop of the relative expansion, which, however, does not reach the value 0, as mentioned in references, but only a value of 0,1 to 0,5.

The solidus line forms the boundary of the lower plasticity. The aluminum alloys in solid-liquid state have a temperature interval of low plasticity near the solidus line. The extent of this interval as well as the absolute values for the relative expansion beyond the solidus line depend on the chemical composition of the alloys.

The impurities of iron and silicon influence the plasticity of the aluminum alloys in solid-liquid state to a great extent. There are 1 figure and 10 references, 8 of which are Soviet.

TITLE: The Hot-shortness Zone in Billets Cast Semi-continuously (O
zone goryachelomkosti v slitkakh polunepryvnogo lit'ya)

PERIODICAL: Izv. vyssh. uchebn. zavedeniy. Tsvetn. metallurgiya, 1958,
Nr 1, pp 130-137

ABSTRACT: Measurement is made of the mechanical properties of Al
alloy V-95 with various amounts of contaminants at tempera-
tures near the solidus by a method making it possible to con-
duct testing to failure with determination of elongation per
unit length in the effective interval of crystallization (a de-
scription of the apparatus is provided). It is found that the
tendency of an alloy to hot cracks in semi-continuous cast bil-
lets is primarily dependent upon its plasticity in the effective
interval of crystallization and is not governed by its strength
in that interval. In the transition region of the billet it is pos-
sible to distinguish a zone of hot shortness. A broadening of
that zone carries with it a danger of hot-crack formation. The
size of that zone depends upon casting speed, the height of the

Card 1/2

SOV/137-58-10-20780

The Hot-shortness Zone in Billets Cast Semi-continuously

crystallizer mold, and the chemical composition of the alloy. A diminution in Si contents and increase in Fe contents narrows the zone of hot shortness and increases the resistance of V-95 alloy to hot-crack formation.

TITLE: Study of the crystal structure of molybdenum disulphide prepared by different methods

PERIODICAL: Kristallografiya, 1961, Vol.6, No.3, pp.389-394

TEXT: The crystal structure of powdered MoS₂ prepared by five different methods has been investigated by X-ray analysis. Sample one was formed by the interaction of molybdenum trioxide with sulphur in fused soda; sample two by the interaction of calcium molybdate with sulphur in fused soda; sample three by the interaction of molybdenum pentachloride with hydrogen sulphide; sample four by the interaction of molybdenum trioxide with sulphur vapour and sample five by the interaction of molybdenum with sulphur vapour. Further samples were also tested - sample six obtained by the thermal dissociation of molybdenum trisulphide and sample seven obtained by the interaction of molybdenum and sulphur and hot-pressed at 1200 to 1300°C. The X-ray photographs of these samples show that the structure of all the synthetic samples is a

Card 1/4

Study of the crystal ...

new type different from both hexagonal α -MoS₂ and rhombohedral β -MoS₂. Fig.3 is a comparison of the results of X-ray studies for the three types of structure (a - α -MoS₂, 6 - β -MoS₂, 8 and 2 new structural type). Since the interplanar distance is the same in going from one form to another, it can be assumed that the layered lattice and the disposition of the sulphur atoms around the molybdenum is retained. It is proposed that the new form is hexagonal with c greater than in the lattice of β -MoS₂. Changes can be seen in the new structure depending on its method of preparation. This is explained by statistical interchanging of hexagonal and rhombohedral packing. The lubricating properties of the artificial MoS₂ are not different from those of natural MoS₂. There are 3 figures, 1 table and 11 references: 2 Soviet-bloc and 9 non-Soviet-bloc. The two references to English language publications read as follows: S.S.Berzelius. Pogg. TITLE: Recrystallization and polygonization during annealing
of dendritic single crystals of pure aluminium

PERIODICAL: Fizika metallov i metallovedeniye, v. 12, no. 5, 1961,
728-731

TEXT: In the case of dendritic recrystallization, single
crystals with an imperfect structure are produced. The branches
of the growing dendrite are very fine and can easily be deformed
and, therefore, the individual areas of the single crystal are
considerably disoriented relative to each other. Also the content
of soluble admixtures is lower in the axes than in the spaces
between the axes of the dendrites even in the case of pure aluminium. X
The authors studied the processes taking place during
annealing of dendritic single crystals of 99.994 wt.% purity
aluminium by means of microscopic investigation of the etch
patterns. The dendritic structure was produced by heating the
single crystals to 2-3°C above the melting point, followed by
cooling with the furnace, during which the temperature gradient

Card 1/2

Recrystallization and ...

32655
S/126/61/012/005/014/028
E073/E535

along the specimens did not exceed 1°C. The specimens were on a flat base and during the heating above the fusion point and after recrystallization their surface remained almost entirely planar. The etch patterns revealed that annealing of dendritic single crystals of aluminium of 99.994 wt.% purity at 500°C produced seedless recrystallization (recrystallization *in situ*), in addition to equalizing diffusion. At 600°C polygonization was observed in the "recrystallized" dendritic single crystals. The distribution and the magnitude of the etch patterns enable estimating the relative speeds of the two processes which occur simultaneously during annealing, namely, polygonization and equalizing diffusion. There are 6 figures and 4 references: 1 Soviet-bloc and 3 non-Soviet-bloc. The English-language references read as follows: Ref.3: Lacombe P., Beaujard L.J. *Inst. TITLE: Channels and macroscopic etch patterns in pure monocrystalline aluminum

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 143, no. 2, 1962, 316 - 318

TEXT: The Bridgman technique was used to grow spherical aluminum single crystals in a device that allowed the cooling rate and the axial temperature gradient of the growing crystal to be regulated. At high cooling rate and small axial temperature gradient there is a large subcooling zone in front of the crystallization zone, i. e., dendritic structures may develop in front of the crystallization zone. Crystals grown in this way exhibit no external defects, but their density is insufficient. If such single crystals are etched for 20 to 50 min in an acid mixture of HNO_3 (47 parts), HCl (50 parts), and HF (3 parts), large etch patterns will occur: holes of regular shape, which are bounded by faces with minimum rate of dissolution: {100}, {110}, or {111}. The

TITLE: Cutting of aluminum single-crystals without deformation

PERIODICAL: Zavodskaya laboratoriya, v. 29, no. 2, 1963, 189-193

TEXT: The cutting of aluminum single crystals by chemical etching with HF and with the aid of a reciprocating "Ftorlon" (fluoro ethylene) twisted thread, 0.12 - 0.17 mm thick, is described. The mechanism for the thread motion was designed according to R. W. Armstrong, R. A. Rapp (Rev. Sci. Instrum., 29, no. 5, 433 (1958)). Depending on the composition of the etching agent the thread was usable for 1.5 - 3 hrs. Dissolution proceeded very slowly in 40% HF and produced a rough surface. A smooth surface and faster cutting were obtained with 60 ml concentrated HF + 0.5ml concentrated HCl + 1.6 g FeCl₃·6H₂O. The surface was not deformed. After additional electropolishing the crystal substructure could be studied metallographically and by x-ray analysis. Deficiencies of the apparatus led to a lateral shift of the thread, thus slightly corrugating the surface. To obtain plane surfaces, single crystals were cut mechanically

Cutting of aluminum single-crystals ,..

B101/B186

by 0.5 mm thick corundum disks on a soft vulcanite base. The disk diameter was 100-125 mm, the speed of rotation 6500 rpm, the feed 1100, 272, 58, or 17 μ /min. At 1100 and 272 μ /min, a polycrystalline layer was formed which was only 50-60 μ thick at a feed rate of 272 μ /min and which could be removed by electropolishing. The apparatus described permits of cutting platelets only 1 mm thick and, with the aid of two corundum disks, plane-parallel platelets as thin as 2 mm. There are 4 figures and 1 table.

AUTHOR: Indenbaum, G. V.; Fishman, Yu. M.

TITLE: Distribution of dislocations and impurities of monocrystals of aluminum, obtained under conditions of unbalanced congealing, and their behavior during annealing

SOURCE: Fizika metallov i metallovedeniye, vol. 17, no. 3, 1964, 419-427

TOPIC TAGS: dislocation, distribution, impurity distribution, aluminum, aluminum monocrystal, unbalanced congealing, annealing, etching, x-rays spectrometer, defraction x-ray microscopy

ABSTRACT: In this paper, the authors developed methods for the exposure of dislocations with the aid of selective etching. An x-ray dual crystal spectrometer of a higher resolving power and defraction x-ray microscopy according to the Schulz method (Schulz, L. G. Trans. AIME, 1954, v. 200, p. 1082) are used for evaluation of disorientations, and the degree of perfection. In the course of investigating the application of etchers, the authors found compounds which yielded excellent results in the exposure of unity boundaries in aluminum crystals with a purity of from 99.992 to 99.996 wt-% (40% HNO₃ = (14-17)% HCl = (41-44)% Butyl Cellosolv = 2% HF.)

Cord | 1/2

ACCESSION NR: AP4029001

(The purer aluminum, the more HCl is required). The results of these spectral analyses of purity of the crystals in question are presented in a table. Micro-photographs of these structures are given. The behavior of dislocations during annealing of samples after crystallization, and the interaction of dislocation with impurities are investigated. In conclusion, the authors propose a high resolution metallographic method for exposing the dislocation structure of aluminum crystals. The character of corrosion and the localization of corrosion in dislocation of 6 to 8% HCl are associated with the shape of the iron impurity in the solid solution of aluminum and iron. The substructure of crystals during the cell growth is thermally relatively stable. The authors express their gratitude to I. I. Novikov for his participation in the evaluation of this paper. Orig. art. has: 9 figures, 1 table.

TITLE: Production of pure aluminum single crystals by the "deformation-annealing" method, and their substructure

SOURCE: Fizika metallov i metallovedeniye, v. 17, no. 5, 1964, 719-725

TOPIC TAGS: aluminum single crystals, deformation, annealing, crystal substructure, lattice distortion, impurity substructure

ABSTRACT: The method of growing aluminum single crystals by recrystallization after a small (critical) deformation was studied in order to supplement the existing data on this method. Main attention was given to the study of the initial state of the samples (size 5 x 10 x 75 mm or 10 x 10 x 75 mm), to the amount of preliminary deformation (cold rolling), to annealing conditions and to the effects of these factors on the size of the recrystallized grains. For the best results the samples (in the initial state) should be fully recrystallized after their deformation by cold rolling and should consist of grains 3-5 mm in size. Uniaxial tension provided the best means for deforming the sample, and it produced optimal results at the deformation ranging from 1.2 to 1.8%. The terminal annealing was attained by

Card 1/32

ACCESSION NR: AP4039599

decreasing the heating rate in the interval of 450-560°C so as to produce a temperature increase of 100°C in 24 hours. This was followed by holding the samples at 600-640°C for 1.5-2.0 hours. The whole cycle of the final annealing proceeded automatically and lasted 48 hours. Structural changes in the sample were studied by etching and by x-ray analyses. The results showed that the appearance of multiple subboundaries (defective structure) was determined by annealing conditions. For example, rough base-plate surface with a depression of 15 microns 20 mm long produced lattice curvature of 20'. At a high temperature this led to the grain polygonization. Thermal stresses were regarded as another possible source of the lattice distortion. The x-ray diffraction patterns obtained by the Schultz method revealed certain lattice distortions which were ascribed to an uneven distribution of impurities in the sample. The pattern of the impurity distribution along the former grain boundaries persisted after the terminal annealing. However, microscopic study revealed that these segregations did not represent the disorientation boundaries. "The authors express their appreciation to N. M. Bliznyukova and N. L. Sherbaum who participated in this work." Orig. art. has: 6 figures.

TITLE: The nature of the effects of the critical degree of deformation in aluminum

SOURCE: Fizika metallov i metallovedeniye, v. 17, no. 6, 1961, 909-916

TOPIC TAGS: critical deformation, aluminum, slippage, relief, recovery, lattice distortion, boundary dislocation, grain growth

ABSTRACT: There is much controversy on the subject of critical deformation and, therefore, the author undertook a study of deformation in $5 \times 10 \times 75$ high-purity Al specimens. Annealed specimens were reduced to 75% at 550°C for 90 minutes. The X-ray diffraction method as well as metallographical analysis were used. At room temperature the mechanism of the initial stage of plastic deformation did not qualitatively differ from that of deformation above the critical point while the structure occurs in the reverse. At temperatures between 450°C and 525°C the intensive temperature rise is observed in specimens with a 2 to 20 mm grain size is accompanied by boundary dislocation of the original grains which results in partial relief of work-hardening. Complete relief was observed at 535 to 560°C by fiber

polygonization which prevents recrystallization or by regular recrystallization during the process. Crystal formation occurs at the sites of the greatest lattice distortions and since the new crystals have a high degree of perfection, they absorb earlier nuclei and the recovered original grains. The peak on the diagram plotted for the effects of deformation at low strain application on the size of recrystallized grains is independent of the critical changes that take place in the nature of the deformation and recrystallization processes. The effect of critical deformation may be connected with the normal recrystallization processes in accordance with the state and the size of the original grains and annealing conditions. This applies to nucleation and to the growth of new crystals from a small number of centers as well as to the growth of a small number of original grains as a result of boundary migration under a large angle in the deformed matrix. This is all the more probable, the smaller the size of the original grains and the higher the rate of heating during annealing. The author gratefully acknowledges the contribution of N. M. Bliznyukova, N. M. Sherbaeva and V. I. Tiraspol'skiy. Orig. art. has 4 figures.

TITLE: Plastic deformation of alloy in solid-liquid condition

SOURCE: AN SSSR. Izvestiya. Metally, no. 5, 1966, 107-110

TOPIC TAGS: aluminum alloy plastic deformation, solid liquid state deformation, aluminum copper silicon alloy, alloy phase diagram, aluminum base alloy, solid state, liquid state, ductility, tensile strength, elongation

ABSTRACT: The effect of quantity of liquid phase on the ductility of aluminum alloy containing 2% copper and 2% Si has been investigated. Specimens 3 mm in diameter, homogenized at 0.92 melting temperature and electrolytically polished, were subjected to tensile test in the temperature interval between solidus and liquidus. Above the solidus temperature, the binary eutectic ($\alpha + \text{Si}$) begins to melt and appears as liquid phase on grain boundaries causing embrittlement of alloy. From the solidus temperature to 560°C, the amount of binary/eutectic changes insignificantly, there is little liquid phase between grains, no sliding along grain boundaries develops and the elongation has approximately zero value. At 570°C, the melting of binary eutectic is

Card 1/2

L 08298-67

ACC NR: AP6031720

ended and aluminum-base solid solution begin begins to melt. Above 590°C, intensive melting and sliding along grain boundaries occurs and elongation increases. Curves of the temperature dependence of the total elongation and the elongation caused by slip along grain boundaries almost coincide in the entire temperature range (560—600°C) which confirms that the contribution of cracking to total elongation is insignificant. The elongation depends primarily on the amount of liquid phase in the alloy. X-ray diffraction analysis also confirmed that grain sliding proceeds on the liquid interlayers. Without liquid interlayers, under conditions of short term tensile tests, the main contribution to total deformation occurs inside the grains, not between them. Orig. art. has: 3 figures.

TITLE: The Automatic Retarder for the Cage Hoisting Machine
(Avtomatischeskiy zamedlitel' kletevoy pod'yemnoy
mashiny.)

PERIODICAL: Gornyy zhurnal, 1959, Nr 3, pp 26-30 (USSR)

ABSTRACT: In 1949, to avoid possible accidents with cage hoisting installations in mines, an obligatory slowing down of the hoisted cage was prescribed every time the cage reached a new level. These delays caused big losses in working time and, in 1958, the author proposed a new system. Cage hoisting installations in main shafts of the Degtyarka copper mine have been equipped with automatically controlled installations which slow down the hoisting cage only at that level where setting cams have been pushed forward. (figures 1 and 2). This system (described in detail increases the productivity of hoisting operations by 30 %, and
